Compilation

TEACHING ASSISTANT: DAVID TRABISH

Administration

- Final grade:
 - Exam: 50%
 - Project: 50%
- For technical questions, please use the course forum
 - Moodle
- Reception time:
 - Wednesday 17:00 1800
 - davidtr1037@gmail.com
 - CheckPoint 246

Course Project

- Build a compiler for an OOP Programming Language
 - Simplified version of known programming languages
- Consists of 4 exercises
- Implement in Java
- Work in groups of 3-4 students
- Constitutes **50%** of the final grade

Submission Guidelines

- Submission with github
 - Each group should create a private repository
- Exercises submissions will be tested on **nova**
- Recommended development environment:
 - Ubuntu
 - Windows users can install a VM

Books

- Modern Compiler Implementation in C
 - Andrew W Appel
- Compilers: Principles, Techniques, and Tools
 - Aho et al.
- Modern Compiler Design
 - Grune et al.

What is compilation?

Translation of code (text) to executable code (machine code)

```
%rbp
                                       push
                                              %rsp,%rbp
                                       mov
                                              %edi,-0x4(%rbp)
                                       mov
int foo(int x, int y) {
                                              %esi,-0x8(%rbp)
                                       mov
    return x + y;
                                              -0x4(%rbp), %edx
                                       mov
                                              -0x8(%rbp),%eax
                                       mov
                                       add
                                              %edx,%eax
                                              %rbp
                                       pop
                                       retq
```

Common compilers

- GCC, LLVM, MSVC
- GCC and LLVM are both open source
- Very useful as an implementation reference....
 - LLVM specially...

Compilation Steps: Frontend

- Lexical analysis
 - Check the validity of tokens
- Syntax analysis
 - Check the syntactic structure
- Semantic analysis
 - Make sure it makes sense

These steps don't depend on the compilation target!

Compilation Steps: Backend

- Intermediate Code Generation
 - Can't be executed...
- Machine code generation
 - Naive register allocation (as if we had infinitely many registers)
 - Finite register allocation (real world scenario)

Lexical Analysis

Lexical Analysis

- The code text consists of *tokens*
- We need to check the **validity** of these *tokens*

Valid Tokens in C

| Token | Examples |
|-------------------|--------------------------|
| Constants | 12, 0x1234, 1.7, 2e+8 |
| Identifiers | var, tmp1 |
| Reserved Keywords | if, while, int, char, do |
| Parentheses | (,) |
| Binary Operators | +,-,*,/ |
| Unary Operators | -,* |
| Comments | /* */, // |

```
void f(int a) {
    6;
}
```

```
void f(int a) {
    6;
}
```

```
void f(int a) {
    6b;
}
```

```
void f(int a) {
    6b;
}
```

Invalid

```
void f(int a) {
    0x;
}
```

```
void f(int a) {
     0x;
}
```

Invalid

```
void f(int a) {
    0u;
}
```

```
void f(int a) {
    0u;
}
```

```
void f(int a) {
```

```
void f(int a) {
```

```
void f(int a) {
    x = 1;
}
```

```
void f(int a) {
    x = 1;
}
```

```
void f(int a) {
    x 1;
}
```

```
void f(int a) {
    x 1;
}
```

```
void f(int a) {
    x 1
}
```

```
void f(int a) {
    x 1
}
```

```
void f(int a) {
    1 = x;
}
```

```
void f(int a) {
    1 = x;
}
```

Invalid

```
void f(int a) {
   int @gmail = 0;
}
```

```
void f(int a) {
   int @gmail = 0;
}
```

Invalid

```
void f(int a) {
    127.0;
}
```

```
void f(int a) {
    127.0;
}
```

```
void f(int a) {
    127.0.0.1;
}
```

```
void f(int a) {
    127.0.0.1;
}
```

Invalid

```
void f(int a) {
    123e;
}
```

```
void f(int a) {
    123e;
}
```

Invalid

```
void f(int a) {
    0xcafecafe;
}
```

```
void f(int a) {
    0xcafecafe;
}
```

```
void f(int a) {
   int x = 0x00000000000000000;
}
```

```
void f(int a) {
    void g() {};
}
```

```
void f(int a) {
    void g() {};
}
```

Detecting Numerical Constants

- We want an **efficient** algorithm for detecting numerical constants
- Can you use a dictionary?
 - Probably not...
 - Too many values to store

Using Regular Expressions

- We can use regular expressions for that
- Identifiers:
 - [a-zA-Z][a-zA-Z0-9]*
- Hex-decimal constants:
 - [0][xX][0-9a-fA-F]+
- Floats
 - ... ?

Every token can be represented using a regular expressions.

Using Regular Expressions

- But what is the actual algorithm?
- The plan is:

Regular Expressions: Reminder

Given an alphabet Σ , the regular expression R represents the language L(R) as follows:

- Atomic expressions:
 - $L(a) = \{a\}, L(\epsilon) = \{\epsilon\}, L(\emptyset) = \emptyset$
- Concatenation:
 - $L(R_1R_2) = \{w_1w_2 \mid w_1 \in L(R_1), w_2 \in L(R_2)\}$
- Union:
 - $L(R_1|R_2) = L(R_1) \cup L(R_2)$
- Kleene Star:
 - $L(R^*) = {\epsilon} \cup L(R) \cup L(RR) \cup ...$

DFA: Reminder

A deterministic finite automaton M is a tuple: $(Q, \Sigma, \delta, q_0, F)$

- Q is a finite set of states
- Σ is a finite set of input symbols
- δ is the transition function: $\delta: Q \times \Sigma \to Q$
- q_0 is the initial states
- *F* is a set of accepting states

A string a_1a_2 ... is **accepted** by M if there is a state sequence s_0s_1 ...:

- $s_0 = q_0$
- $\delta(s_i, a_{i+1}) = s_{i+1} \ (i = 0, 1, ..., n-1)$
- $s_n \in F$

NFA: Reminder

A non-deterministic finite automaton M is a tuple: $(Q, \Sigma, \delta, q_0, F)$

- Q is a finite set of states
- Σ is a finite set of input symbols
- δ is the transition function: $\delta: Q \times \Sigma \to P(Q)$
- q_0 is the initial states
- *F* is a set of accepting states

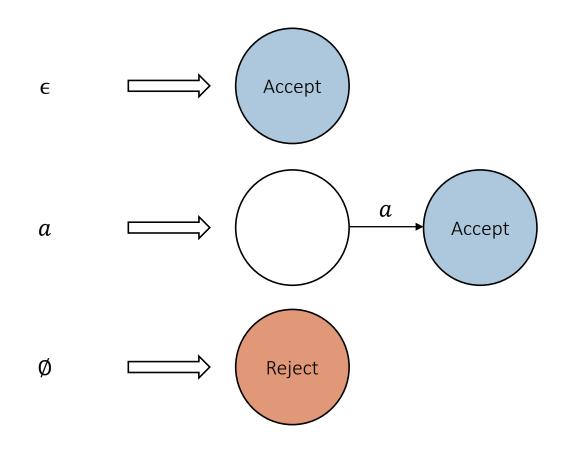

A string a_1a_2 ... is **accepted** by M if there is a state sequence s_0s_1 ...:

- $s_0 = q_0$
- $s_{i+1} \in \delta(s_i, a_{i+1}) \ (i = 0, 1, ..., n-1)$
- $s_n \in F$

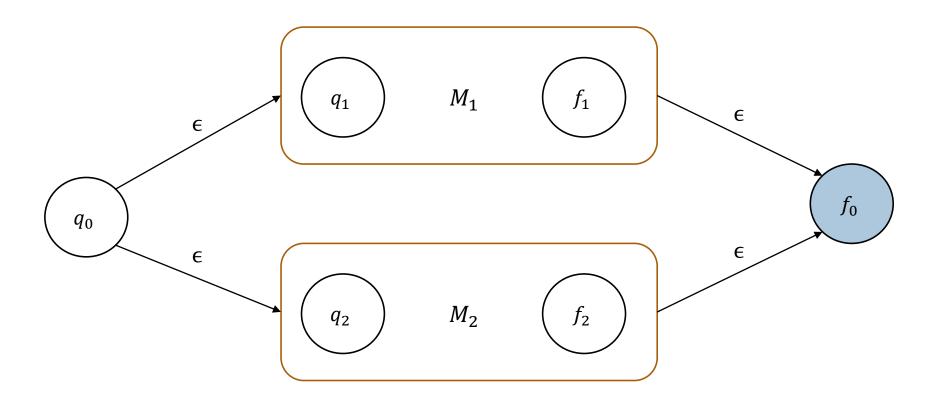

RE to DFA

- For every regular expression, there is a deterministic finite automaton than accepts it's language
 - Proof by construction...
- Once we have the DFA, we can implement using a transition table
 - As done in *Flex*

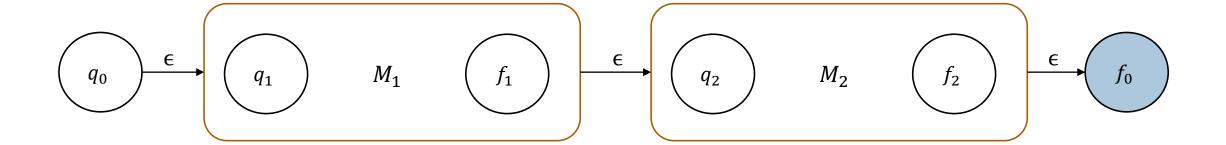

RE to NFA: Atomic Expressions

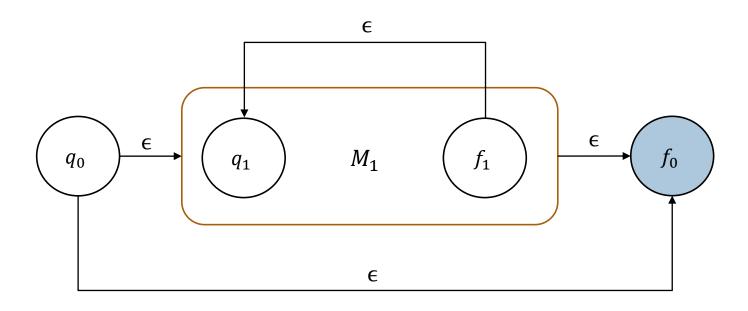

RE to NFA: Union

RE to NFA: Concatenation

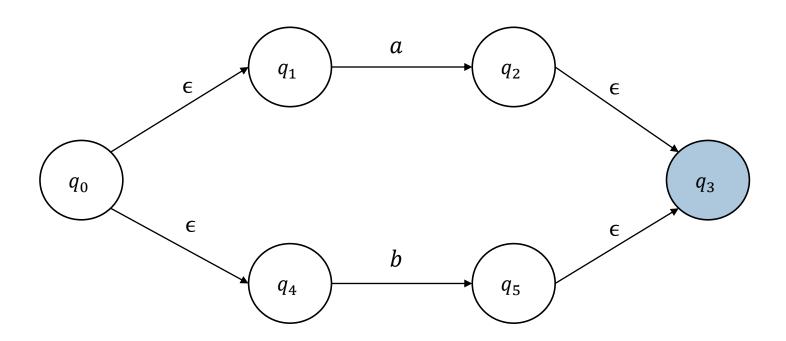

RE to NFA: Kleene Star

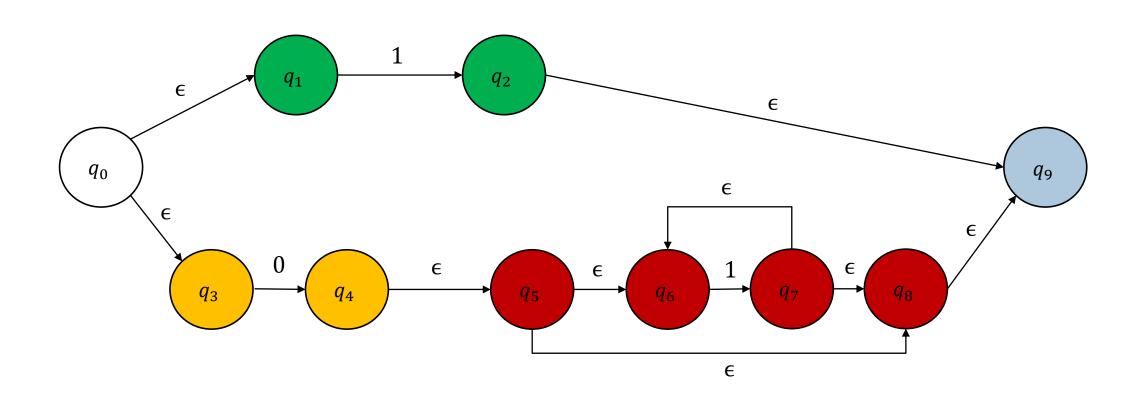

RE to NFA: Example

• NFA for a | b

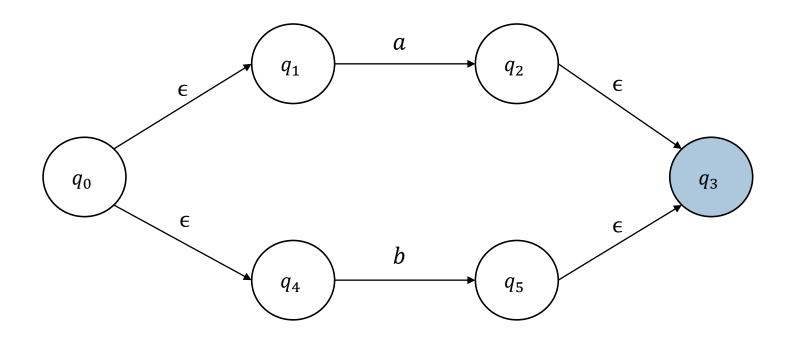

RE to NFA: Another Example

• NFA for $01^* \mid 1$

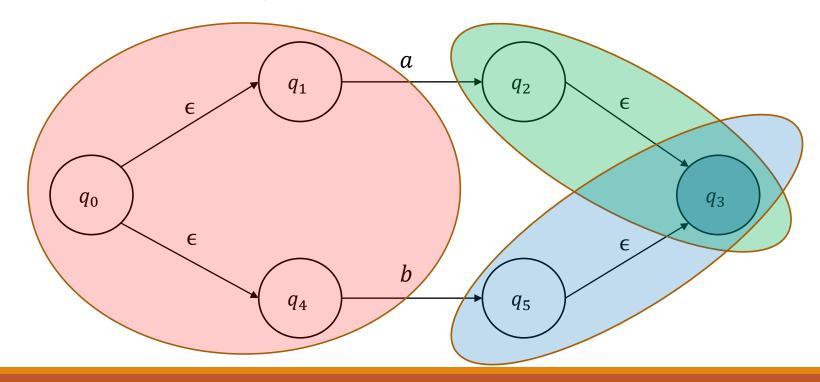

NFA to DFA: Example

- At the beginning, we may be at: q_0, q_1, q_4
- If next token is a then we may be at: q_2 , q_3
- If next token is b then we may be at: q_5 , q_3

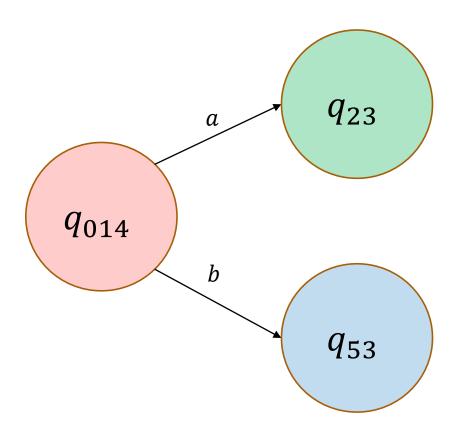

NFA to DFA: Example

- At the beginning, we may be at: q_0, q_1, q_4
- If next token is a then we may be at: q_2 , q_3
- If next token is b then we may be at: q_5 , q_3

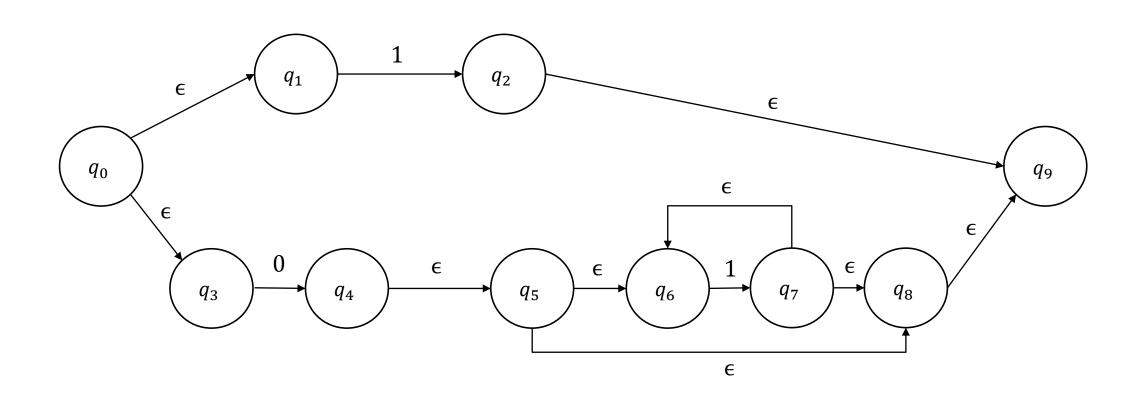

NFA to DFA: Example

• So we can transform to the following DFA:

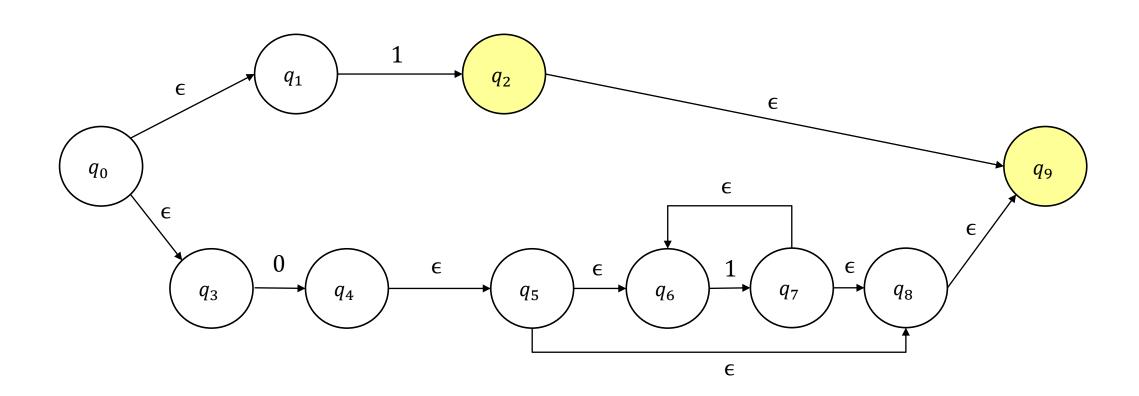

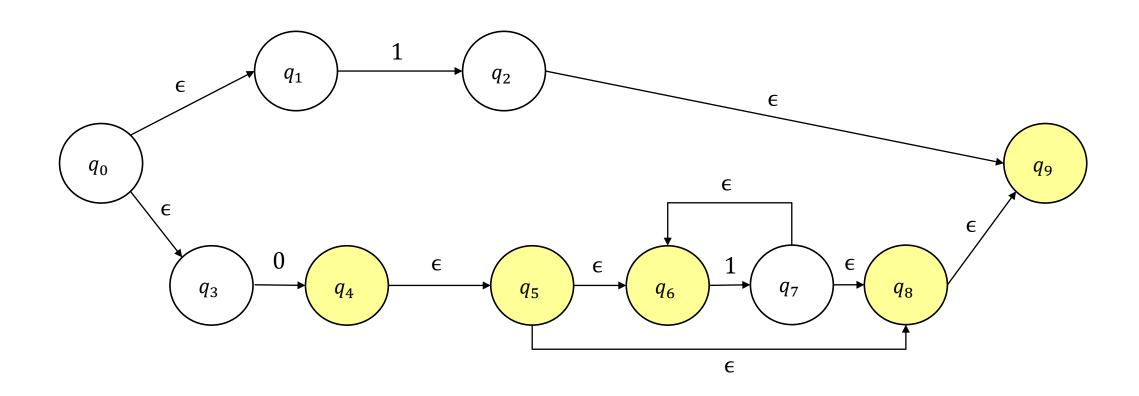

NFA to DFA: Formal Details

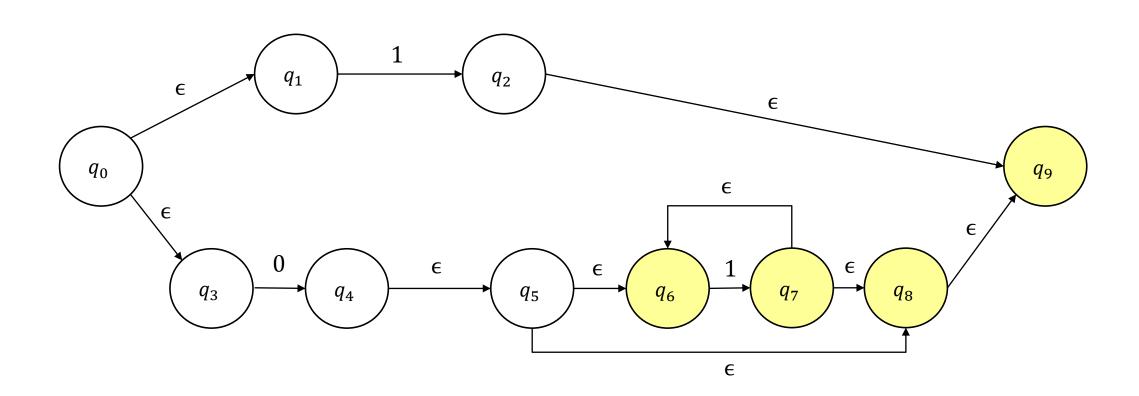

- Let $(Q, \Sigma, \Delta, q_0, F)$ be a non-deterministic finite automaton
- The set of states is the P(Q)
- The initial state is the ϵ -closure of q_0
- For every state in the set (now, a state is a *set of states*):
 - Compute the union over the ϵ -closure of the successor states
- A state is accepting if it contains a set from F

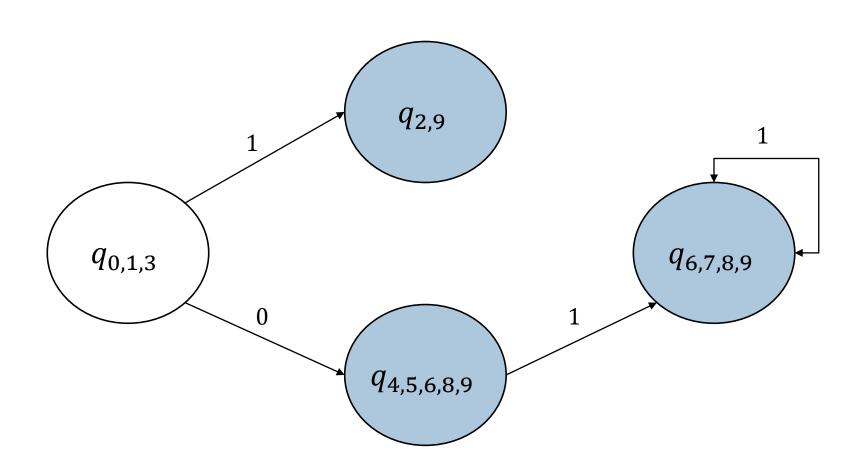

Building a Lexical Analyzer

- Construct a regular expression for token types:
 - Identifiers, numbers, reserved keywords
- If we have a collision (a token is accepted in more than one DFA):
 - Define priority
 - The RE that was defined earlier will take advantage

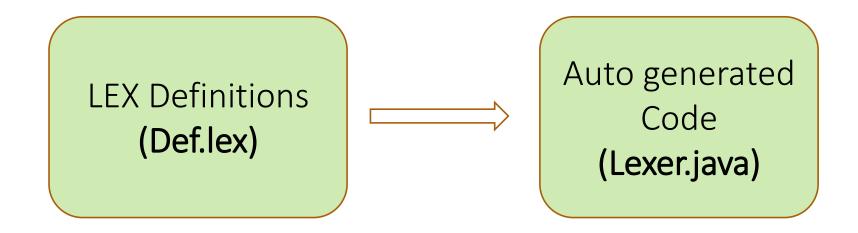

Regular Expressions Definitions for C

- Here we can see the regular expression definitions:
 - http://www.lysator.liu.se/c/ANSI-C-grammar-l.html
 - Quite simple and modular...

JFlex

- Java Fast Lexical Analyzer
 - Inspired by the original flex project (written in C)
- Accepts an input file with tokens definitions
- Generates Java code is the exported function yylex
- This **yylex** function reads the input and returns:
 - The type of the read token
 - Or an error...

JFlex

Example: Counting Lines

How can we use JFlex to count lines for a given input file?

```
%{
private Symbol symbol(int type) { return new Symbol(type, yyline, yycolumn); }
public int getLine() { return yyline + 1; }
public int getTokenStartPosition() { return yycolumn + 1; }
public int lines_count = 0;
%}
NEWLINE = \ln | r 
ANY = .*
%% // separator...
<YYINITIAL> {
{NEWLINE} { lines_count++; }
{ANY} { }
<<EOF>> { return symbol(TokenNames.EOF);}
```

User define code/handlers:

```
%{
private Symbol symbol(int type) { return new Symbol(type, yyline, yycolumn); }
public int getLine() { return yyline + 1; }
public int getTokenStartPosition() { return yycolumn + 1; }
public int lines_count = 0;
%}
```

Regular expressions definitions:

```
NEWLINE = \n | \r\n
ANY = .*
```

Putting it all together:

```
<YYINITIAL> {
{NEWLINE} { lines_count++; }
{ANY} { }
<<EOF>> { return symbol(TokenNames.EOF);}
}
```

Counting Lines: Tokens Definitions

```
public interface TokenNames {
    /* terminals */
    public static final int EOF = 0;
}
```

Counting Lines: Main

- Consider the following flex-like definition:
 - a*b { print "1" }ca { print "2" }a*ca* { print "3" }
- What will the lexer print for the input:
 - abcaacacaaabbaaabcaaca

Consider the following flex-like definition:

```
a*b { print "1" }ca { print "2" }a*ca* { print "3" }
```

- What will the lexer print for the input:
 - abcaacacaaabbaaabcaaca
- Answer:

•

```
void f(int a) {
   int i = 8;
   int j = 3;
   i--+--j;
}
```

```
void f(int a) {
   int i = 8;
   int j = 3;
   i--+--j;
}
```

Valid

```
void f(int a) {
   int i = 8;
   int j = 3;
   i----j;
}
```

```
void f(int a) {
   int i = 8;
   int j = 3;
   i----j;
}
```

Invalid

```
void f(int a) {
   int i = 8;
   int j = 3;
   (i--)-(--j);
}
```

```
void f(int a) {
   int i = 8;
   int j = 3;
   (i--)-(--j);
}
```

Valid

```
void f(int a) {
   int i = 8;
   int j = 3;
   i---(--j);
}
```

```
void f(int a) {
   int i = 8;
   int j = 3;
   i---(--j);
}
```
